

## Project Writeup

**Project Name:** Validation Of Email

**Project Description:**

The simplest regular expression to validate an email address is “`^(.+)@(\S+) $`”.

It only checks the presence of the @ symbol in the email address. If present, then the validation result returns *true* otherwise, the result is *false*. However, this regular expression doesn't check the local part and domain of the email.

the Email validation program is executed by using the following methods:

1. Method to validate whether the given email id is correct or not.
2. Main method to implement the method.
